Data Communications & Networks

Session 7 – Sub-Topic 1
Discrete Event Simulation in PNSimulator

Dr. Jean-Claude Franchitti

New York University
Computer Science Department
Courant Institute of Mathematical Sciences
Events are unique and represent an arrival of some new information into the system. For example:

- Packet arrives from the link layer
- Timer expires
- Application generates a message
- User closes an application
Events have a defined position in time in relation to other events

- **Causal Relationship**
  - One event cannot occur unless another event has already occurred
  - If Event A causes Event B, then A must precede B in time
  - If B, then A

- **Random**
  - An event depends on nothing other than a probability distribution
    - A customer walks into a store
    - An application generates a request
All events are created as “future” events

Based on event and perhaps current state, calculate a time at which the event will occur

Insert event into a time-ordered queue

Remove events from the head of the queue and deliver event:
  - Advance clock to event time
  - Call event handler method
  - Repeat until no more events on queue
Event Generation

- After delivery of an event, call all random event generator:
  - If any random event is to happen, its generator will return an event and future time
- Event handlers can generate events. These are typically causal events
  - Example
    - your send() method is an event handler for the Event SendApplicationMessage
    - *Your send method starts a timer which causes a TimerEvent to be put on queue with future time = now + timeout value*
PNSimulator Events are Atomic

- In PNSimulator, each event is fully handled before any new event handler is called.
- This means that all of your handlers are Threadsafe.
- This does not insure that your code can be shared however! That’s your job.
- What does this mean?
All context dependent variables must be allocated such that any invocation of a handler $L$ for user $N$ can retrieve context($L,N$).

Usually in communications systems $L$ is layer-specific.

For example, sequence numbers in TCP are distinct for each socket.

So you must keep your Node A variables distinct from your Node B variables.
