Patterns…

- « Patterns help you build on the collective experience of skilled software engineers. »
- « They capture existing, well-proven experience in software development and help to promote good design practice »
- « Every pattern deals with a specific, recurring problem in the design or implementation of a software system »

Becoming a Chess Master

- First learn rules and physical requirements
  - e.g., names of pieces, legal movements, chess board geometry and orientation, etc.
- Then learn principles
  - e.g., relative value of certain pieces, strategic value of center squares, power of a threat, etc.
- However, to become a master of chess, one must study the games of other masters
  - These games contain patterns that must be understood, memorized, and applied repeatedly
- There are hundreds of these patterns

Becoming a Software Designer Master

- First learn the rules
  - e.g., the algorithms, data structures and languages of software
- Then learn the principles
  - e.g., structured programming, modular programming, object oriented programming, generic programming, etc.
- However, to truly master software design, one must study the designs of other masters
  - These designs contain patterns that must be understood, memorized, and applied repeatedly
- There are hundreds of these patterns
Software Architecture

- A software architecture is a description of the subsystems and components of a software system and the relationships between them.
- Subsystems and components are typically specified in different views to show the relevant functional and non-functional properties of a software system.
- The software system is an artifact. It is the result of the software design activity.

Component

- A component is an encapsulated part of a software system. A component has an interface.
- Components serve as the building blocks for the structure of a system.
- At a programming-language level, components may be represented as modules, classes, objects or as a set of related functions.
Subsystems

A subsystem is a set of collaborating components performing a given task. A subsystem is considered a separate entity within a software architecture.

It performs its designated task by interacting with other subsystems and components…

Architectural Patterns

An architectural Pattern expresses a fundamental structural organization schema for software systems. It provides a set of predefined subsystems, their responsibilities, and includes rules and guidelines for organizing the relationships between them.
Design patterns

- A design pattern provides a scheme for refining the subsystems or components of a software system, or the relationships between them. It describes a commonly-recurring structure of communicating components that solves a general design problem within a particular context.

Idioms

- An Idiom is a low-level pattern specific to a programming language. An idiom describes how to implement particular aspects of components or the relationships between them using the features of the given language.
Framework

- A framework is a partially complete software (sub-) system that is intended to be instantiated. It defines the architecture for a family of (sub-) systems and provides the basic building blocks to create them. It also defines the places where adaptations for specific functionality should be made.

First Example

- A Dice Game
- A Player rolls 10x 2 dices
- If result = 7, score=score + 10 points
- At the end, score of the player is registred in the highscore table.

Design Stage

- Manage User Interface
- Manage Persistence of highscore in a file or in relational database
- Realize a layered architecture: Apply the Layer Architectural Pattern

Layer

- Helps structure an application that can be decomposed into groups of subtasks in which each group of subtasks is at a particular level of abstraction.
Layer: examples

Layer 1: Transmits bits: velocity, bit-code, connection, etc.
Layer 2: Detects and corrects errors in bit sequences
Layer 3: Selects a route from sender to receiver
Layer 4: Breaks messages into packets and guarantees delivery
Layer 5: Provides dialog control and synchronization facilities
Layer 6: Structures information and attaches semantics
Layer 7: Provides miscellaneous protocols for common activities

Layers : Variants

- **Relaxed Layered System:**
  - A layer « j » can use service of j-1, j-2…
  - A layer can be partially opaque
    - Some service to layer j+1, others to all upper services…

- **Layering through inheritance:**
  - Lower layers are implemented as base classes
  - Higher level can override lower level…

Layers : Known Uses

- Virtual machines: JVM and binary code format
- API : Layer that encapsulates lower layers

Layers: benefits

- Reuse of layers

- Dependencies are kept local
- Exchangeabilities:
  - Replacement of old implementation with Adapter Pattern
  - Dynamic exchange with Bridge Pattern

Layers: Liabilities

- Cascades of changing behavior

- Unnecessary work: functions of a layer called many times for one service
- Difficulty of establishing correct granularity of layers: Too few layers -> less benefits, too many layers -> complexity and overhead...

Observer

- One-to-many dependency between objects: change of one object will automatically notify observers
Observer: Applicability

- A change to one object requires changing an unknown set of other objects
- Object should be able to notify other objects that may not be known at the beginning

Observer: Structure

Pattern Factory Method

- **Intent**
  - Define an interface for creating an object, but let sub-classes decide which class to instantiate
  - let a class defer instantiation to subclasses
  - Also known as Virtual Constructor

Factory Method

- **Applicability** : Use when
  - a class cannot anticipate the class of objects it must create
  - a class wants its subclasses to specify the objects it creates
  - classes delegate responsibility to one of several helper subclasses, and you want to localize the knowledge of which helper subclass to delegate.
Factory method

- **Consequences**
  - Provide hooks for subclasses
  - connects parallel class hierarchies

- **Known uses**
  - MacApp, ET++
  - ClassView in smalltalk80 MVC (controller creation)
  - Orbix ORB for generating PROXY object
« Persist » Layer

- Persistence technical classes
- Ensure independence of Core/Persist
  - Be able to switch « persistent engine »
- For example:
  - Persistence via « Serialization »
  - Persistence via a relational database (JDBC).

Summary

  - Combining pattern to combine their forces…
Bank example…

- A basic bank system:
  - 1 bank, n Account.
  - Each account belong to 1 client.
  - Each account is credited by an amount a money.

- Bank functions
  - Withdrawal on an account, Credit an account,
    Transfer money from one account to another…

Applying Command Pattern…

- Encapsulate a request as an object, thereby letting you parameterize clients with different requests, queue or log requests, and support undoable operations.

Command Example
Command Example

```
Application
  Add(document)
  application

OpenCommand
  Execute() Q
  AskUser()

name = AskUser()
if (=document�新文件)
  application->Add(doc)
  doc->Open()
```

Command Structure

```
Client
  Invoker
    Command
      Execute()

Receiver
  Action()

ConcreteCommand
  Execute()
  state
  receiver->Action()
```
Command Structure

Command Consequences

- Command decouples the object that invokes the operation from the one that knows how to perform it.
- Commands are first-class objects. They can be manipulated and extended like any other object.
- It's easy to add new Commands, because you don't have to change existing classes.
Applying Command Pattern
Composite Pattern

- Compose objects into tree structures to represent part-whole hierarchies. Composite lets clients treat individual objects and compositions of objects uniformly.

And So on…

- Storing state: Memento Pattern
- Observing Account: Observer Pattern
- Visiting all object graph: Visitor Pattern
- Remote access: Proxy pattern
- ...

Proxy Pattern

- Provide a surrogate or placeholder for another object to control access to it.
Proxy Example

Proxy Structure
Proxy benefits

- remote proxy can hide the fact that an object resides in a different address space.
- A virtual proxy can perform optimizations such as creating an object on demand.
- Both protection proxies and smart references allow additional housekeeping tasks when an object is accessed.
Adapter Pattern

- Convert the interface of a class into another interface clients expect. Adapter lets classes work together that couldn't otherwise because of incompatible interfaces.

Adapter Example
Visitor Pattern

- Represent an operation to be performed on the elements of an object structure. Visitor lets you define a new operation without changing the classes of the elements on which it operates.
Visitor example

---

Visitor example

---
Visitor applicability

- many distinct and unrelated operations need to be performed on objects in an object structure, and you want to avoid "polluting" their classes with these operations.

Visitor Structure
Visitor Structure

Visitor Consequences

- Visitor makes adding new operations easy
- A visitor gathers related operations and separates unrelated ones
- Adding new Concrete Element classes is hard
- Visiting across class hierarchies
- Accumulating state.
- Breaking encapsulation
Chain of responsibility

- Avoid coupling the sender of a request to its receiver by giving more than one object a chance to handle the request. Chain the receiving objects and pass the request along the chain until an object handles it.
Chain of Responsibility

Chain of Responsibility

Client → Handler

ConcreteHandler1

ConcreteHandler2

successor

handleRequest()
Participants

- **Handler (HelpHandler)**
  - defines an interface for handling requests.
  - (optional) implements the successor link.
- **ConcreteHandler (PrintButton, PrintDialog)**
  - handles requests it is responsible for.
  - can access its successor.
  - if the ConcreteHandler can handle the request, it does so; otherwise it forwards the request to its successor.
- **Client**
  - initiates the request to a ConcreteHandler object on the chain.

Example…

- **Awt 1.0**
Strategy

- Define a family of algorithms, encapsulate each one, and make them interchangeable. Strategy lets the algorithm vary independently from clients that use it.
Strategy

- declares an interface common to all supported algorithms. Context uses this interface to call the algorithm defined by a ConcreteStrategy.

ConcreteStrategy (SimpleCompositor, TeXCompositor, ArrayCompositor)
- implements the algorithm using the Strategy interface.

Context (Composition)
- is configured with a ConcreteStrategy object.
- maintains a reference to a Strategy object.
- may define an interface that lets Strategy access its data.

Participants
State

- Allow an object to alter its behavior when its internal state changes. The object will appear to change its class.
Example

Structure
Consequences

1. *It localizes state-specific behavior and partitions behavior for different states*
2. *It makes state transitions explicit*
3. *State objects can be shared*

Decorator

- Attach additional responsibilities to an object dynamically. Decorators provide a flexible alternative to subclassing for extending functionality.
Example

Some applications would benefit from using a more flexible approach, but a more rigid design would be preferable.

For example, most document editors need to support formatting and editing tools for some subset of the text. However, they generally also contain non-programmers who use the software to produce written documents. The design could provide flexibility to support both groups of users.

Example

Text and graphics could be mixed together with...
Applicability

- to add responsibilities to individual objects dynamically and transparently, that is, without affecting other objects.
- for responsibilities that can be withdrawn
- when extension by subclassing is impractical

Consequences

1. More flexibility than static inheritance
2. Avoids feature-laden classes high up in the hierarchy
3. A decorator and its component aren't identical
4. Lots of little objects
Bridge

- Decouple an abstraction from its implementation so that the two can vary independently.
Bridge Structure…

Bridge

1. Decoupling interface and implementation
2. Improved extensibility
3. Hiding implementation details from clients
Builder

- Separate the construction of a complex object from its representation so that the same construction process can create different representations.
Builder Structure...

```java
for all objects in structure {
    builder->BuildPart();
}

Director
  Construct()
  builder

Builder
  BuildPart()

ConcreteBuilder
  BuildPart()
  GetResult()

Product
```

Builder

```java
aClient
  new ConcreteBuilder

new Director(aConcreteBuilder)

Construct()

BuildPartA()
  BuildPartB()
  BuildPartC()

GetResult()
```

121

122
Builder Consequences

1. *It lets you vary a product's internal representation*
2. *It isolates code for construction and representation*
3. *It gives you finer control over the construction process*

FlyWeight

- Use sharing to support large numbers of fine-grained objects efficiently.
FlyWeight

Flyweight: Structure
Flyweight example

Flyweight: Instances
Flyweight: Applicability

- Etat intrinsèque/extrinsèque…
- Les États extrinsèques peuvent être calculés…

Flyweight (il a rien compris… 😊)
Iterator

- Provide a way to access the elements of an aggregate object sequentially without exposing its underlying representation.
Iterator example:

Example
Memento

- Without violating encapsulation, capture and externalize an object's internal state so that the object can be restored to this state later.

Memento Structure...
Memento…

1. Preserving encapsulation boundaries
2. It simplifies Originator
3. Using mementos might be expensive.
4. Defining narrow and wide interfaces
5. Hidden costs in caring for mementos

Case Study
Design problems…

- *Document structure.* The choice of internal representation for the document affects nearly every aspect of Lexi’s design. All editing, formatting, displaying, and textual analysis will require traversing the representation. The way we organize this information will impact the design of the rest of the application.

- *Formatting.* How does Lexi actually arrange text and graphics into lines and columns? What objects are responsible for carrying out different formatting policies? How do these policies interact with the document’s internal representation?

Design problems…

- *Embellishing the user interface.* Lexi’s user interface includes scroll bars, borders, and drop shadows that embellish the WYSIWYG document interface. Such embellishments are likely to change as Lexi’s user interface evolves. Hence it’s important to be able to add and remove embellishments easily without affecting the rest of the application.

- *Supporting multiple look-and-feel standards.* Lexi should adapt easily to different look-and-feel standards such as Motif and Presentation Manager (PM) without major modification.

- **Supporting multiple look-and-feel standards.** Lexi should adapt easily to different look-and-feel standards such as Motif and Presentation Manager (PM) without major modification.

Design problems…

- **Spelling checking and hyphenation.** How does Lexi support analytical operations such as checking for misspelled words and determining hyphenation points? How can we minimize the number of classes we have to modify to add a new analytical operation?
Summary (C. Alexander)

- It is possible to create building architectures by stringing together patterns in a rather loose way. A building made like this, is an assembly of patterns. It is not dense. It is not profound. But it is also possible to put patterns together in such way that many patterns overlap in the same physical space: the building is very dense; it has many meanings captured in a small space; and through this density, it becomes profound.

Pipes and Filters

- Recombining filters allows the building of families of related systems.

Pipes and Filters: push pipeline
Pipes and Filters: pull pipeline

Pipes and Filters: push-pull pipeline
Pipes and Filters: Known Uses

- Unix
- CMS Pipelines (extension IBM mainframes)
- LASSPTools (Numerical Analysis)
  - Graphical input devices (knobs or sliders)
  - Filters for numerical analysis and data extraction
  - Data sinks to produce animation from numerical data streams…

Pipes and Filters Benefits

- No intermediate file necessary (but possible)
- Flexibility by filter exchange
- Flexibility by recombination
- Reuse of filter components
- Rapid prototyping of pipeline
- Efficiency by parallel processing

Pipes and Filters Liabilities

- Sharing state information is expensive or inflexible
- Efficiency gain by parallel processing is often an illusion
  - Cost of data transfer, filters that consume all data before one output, context switch on one computer, synchronization of filters via pipes
- Data transformation overhead
- Error Handling

Presentation-Abstraction-Control

- PAC define a hierarchy of cooperating agents.
- Each agent consists of three components: presentation, abstraction, control.
- Separates human computer interaction from its functional core and its communication with other agents...

Summary (C. Alexander)

- It is possible to build an architecture by stringing together patterns, in a rather loose way. A building made like this, is an assembly of patterns. It is not dense. It is not profound. But it is also possible to put patterns together in such way that many patterns overlap in the same physical space: the building is very dense; it has many meanings captured in a small space; and through this density, it becomes profound.
Drawbacks of Patterns

- Patterns do not lead to direct code reuse.
- Individual Patterns are deceptively simple.
- Composition of different patterns can be very complex.
- Teams may suffer from pattern overload.
- Patterns are validated by experience and discussion rather than by automated testing.
- Integrating patterns into a software development process is a human-intensive activity.
